- 5 AutoML Tools
- 6 Final Remarks
- 7 Bibliography

Automated machine learning (AutoML) is the process of automating the end-to-end process of applying machine learning to real-world problems.

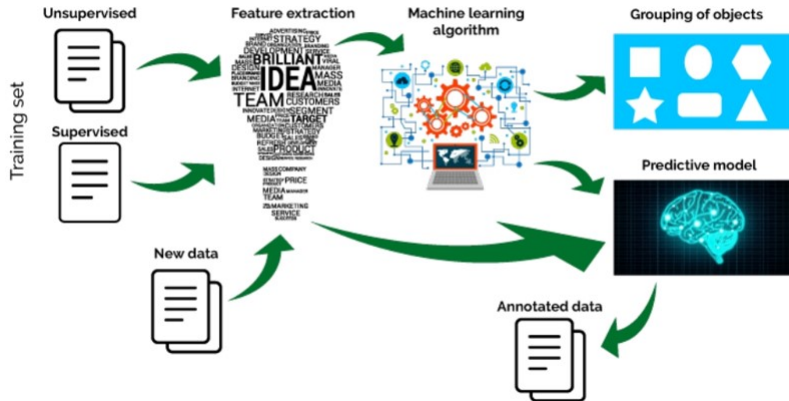

# The Perfect Model Does Not Exist

“All models are wrong,  
but some are useful.”  
–GEORGE BOX, 1919-2013

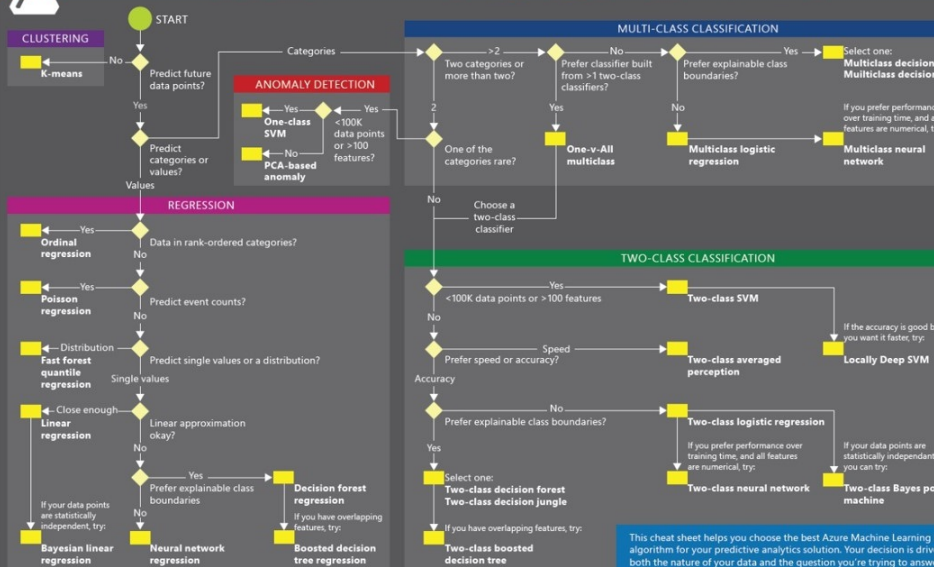

# Machine Learning High-Level Overview

## Machine Learning

# Microsoft Azure Machine Learning: Algorithm Cheat Sheet

This cheat sheet helps you choose the best Azure Machine Learning algorithm for your predictive analytics solution. Your decision is driven both the nature of your data and the question you're trying to answer.

# What is Automated Machine Learning (AutoML)?

*“Machine learning is very successful, **but its successes crucially rely on human machine learning experts**, who select appropriate ML architectures (deep learning architectures or more traditional ML workflows) and their hyper-parameters.*

*As the complexity of these tasks is often beyond non-experts, the rapid growth of machine learning applications has created a demand for off-the-shelf machine learning methods that can be used easily and without expert knowledge.*

*We call the resulting research area that targets progressive automation of machine learning AutoML.”*

<https://sites.google.com/site/automl2016/>

# Why Automated Machine Learning (AutoML)?

- The demand for machine learning experts has outpaced the supply. To address this gap, there have been big strides in the development of user-friendly machine learning software that can be used by non-experts and experts, alike.
- AutoML software can be used for automating a large part of the machine learning workflow, which includes automatic training and tuning of many models within a user-specified time-limit.

# What is NOT Automated Machine Learning (AutoML)?

- AutoML is not automated data science;
- AutoML will not replace Data Scientist;
  - All the methods of automated machine learning are developed to support data scientists, not to replace them.
  - AutoML is to free data scientists from the burden of repetitive and time-consuming tasks (e.g., machine learning pipeline design and hyper-parameter optimization) so they can better spend their time on tasks that are much more difficult to automate.

- Automated Feature Engineering
  - Feature selection
  - Feature extraction
  - Detection and handling of skewed data and/or missing values
- Model Selection
  - Meta learning and transfer learning
- Hyper-parameter optimization

## Interpretability

Ability of users to understand the model, the parameters of the model and their effect on the outcome

- In regression, coefficients enable us to interpret the influence of an independent variable on the dependent variable.  
The standard error of estimates of the coefficients enable us to determine how confident are we on these estimates
- In decision trees a complex decision is a sequence of simple decision

## Parsimonious models

A parsimonious model is a model that accomplishes a desired level of explanation or prediction with as few predictor variables as possible.

- Models that use internal feature selection: decision and regression trees, decision rules
- In regression, using Exhaustive search, Forward search, Backward search or Stepwise regression in model selection

- Greedy Forward Selection
  - Selecting best features iteratively
  - Selecting features based on coefficients of model
- Greedy backward elimination
- Use GBM for normal features
- Random Forest for feature rank

# The Algorithm Selection Problem

- Typically many different algorithms exist in a particular domain (classification, regression, optimization etc.).
- Given a decision problem, We want methods that can help us to select the one with the best performance.
- This problem was first formulated by Rice [1976]:
- For a given problem instance  $x \in P$ , with features  $f(x) \in F$ ,
  - find the selection mapping  $S(f(x))$  into algorithm space  $A$ ,
  - such that the selected algorithm  $\alpha \in A$
  - maximizes the performance mapping  $y(\alpha(x)) \in Y$ .

# The Algorithm Selection Problem

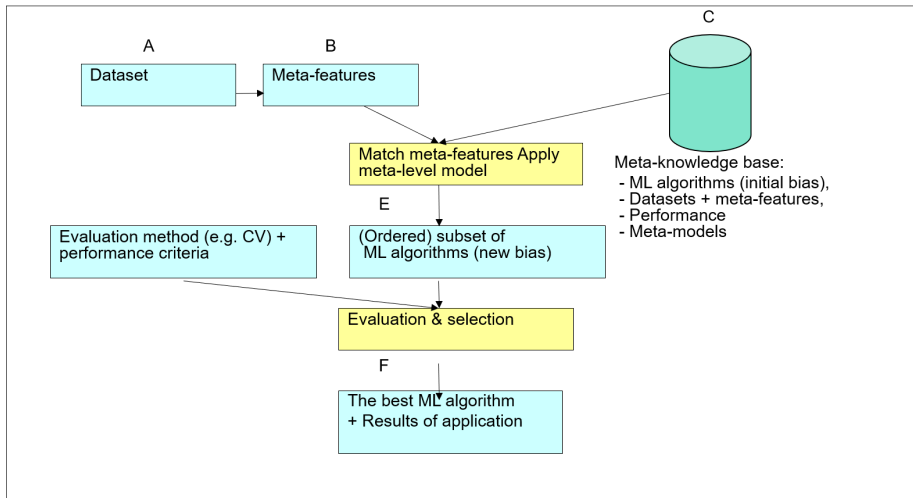

- In subsequent work the selection mapping  $S(f(x))$  was generated using ML methods.
- The process is often referred to as meta-learning.
- The process can be applied to the problem of selecting classification algorithms.

- A large set of techniques is available in Machine Learning (ML).
  - + It increases a possibility that a good solution can be found.
  - – It is much harder to find the right ML algorithm, as many alternatives exist.
- The problem of selecting a suitable (the best) algorithm can be seen as a problem of search.
- We cannot test all ML algorithms for computational reasons (there are thousands of variants of ML algorithm + parameter settings)
- Why meta-learning?
  - It helps to build on previous experience and
  - identify the right algorithm more effectively.
- In this part we focus on classification algorithms.

- Phase 1:
  - Consider the given new dataset, construct characteristics / meta-features.
  - Exploit meta-level model to identify a suitable subset of algorithms.
- In some work the result is a ranked subset of classification algorithms permitting reduced search.
- Phase 2: Search through the reduced space of algorithms.
  - Evaluate each option using
    - a chosen evaluation method (typically a cross-validation) and
    - a given performance criteria (e.g. accuracy).
  - Identify the best alternative (or an algorithm that is comparable).

# Selecting ML Algorithms on Meta-features

- The selection method relies on dataset characteristics or meta-features to provide some information that can differentiate performance of a set of given learning algorithms.
- These typically include :
  - statistical and information-theoretic measures,
  - model based characterization,
  - landmarking

- These measures typically include :
  - number of classes,
  - number of features,
  - ratio of examples to features,
  - degree of correlation between features and target concept,
  - average class entropy
  - etc.
- + Positive and tangible results (e.g., ESPRIT Statlog and METAL).
- – There is a limit on how much information these measures can capture,
  - as these measures are uni- or bi-lateral measures only
  - capture relationships between two attributes only or
  - one attribute and the class.

- Examine performance of a set of simple and fast learning algorithms (land-markers).
- The accuracy of these land-markers is used to characterize the dataset.

- A meta-level system / model helps to map characteristics into classification algorithms.
- The meta-level system / model can be in the form of:
  - meta-level rules,
  - k-NN (on the meta-level),
  - neural network,
  - other type of classification model on the meta-level.

- Early approaches (Rendell & Cho, 1990) used rules, such as:
  - If the given dataset characteristics are  $C_1, C_2, \dots, C_n$  then use algorithm  $A_1$  in preference to algorithm  $A_2$ .

```
IF (# training instance < 737) AND
   (# prototype per class > 5.5) AND
   (# relevants > 8.5) AND
   (# irrelevants < 5.5)
THEN IB1 will be better than CN2
```

One simple approach uses 1-NN :

- Compare meta-level characteristics of the new problem with meta-level characteristics of past problems,
- Identify the most similar dataset
- Retrieve either :
  - The classification algorithm that performed best on that dataset,
  - Ranking of classification algorithms, ordered by performance.

A more complex approach employs k-NN:

- Uses k-NN method to identify the most similar datasets.
- For each of these datasets,
  - retrieves the ranking of the candidate classification algorithms,
  - based on past performance criteria (accuracy, learning time).
- Aggregate the rankings obtained to generate the final recommended ranking of algorithms.
- Evaluate the top N elements in the ranking (Phase II)  
select the one with the best performance.

## Ensemble models

Ensemble methods use multiple learning algorithms to obtain better predictive performance than could be obtained from any of the constituent learning algorithms alone.

# Parameters vs Hyper Parameters

- **Parameters:** Values that can be estimated from data
  - Examples:
    - Regression Coefficients
    - Weights in a Neural Network
- **HyperParameters:** Values external to the model and cannot be learnt from the data
  - Examples:
    - $k$  in k-Means
    - Learning rate in Neural Network
    - Regularization parameters

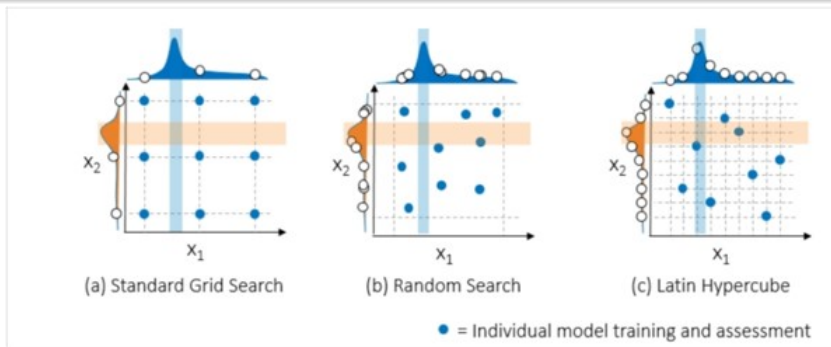

# Hyperparameters

# Hyperparameter optimization

## Hyperparameter optimization

finds a tuple of hyperparameters that yields an optimal model which minimizes a predefined loss function on given independent data

# Hyperparameter optimization

- **Grid search**

an exhaustive searching through a manually specified subset of the hyper-parameter space of a learning algorithm.

- **Random search**

replaces the exhaustive enumeration of all combinations by selecting them randomly.

- **Bayesian optimization**

builds a probabilistic model of the function mapping from hyperparameter values to the objective evaluated on a validation set.

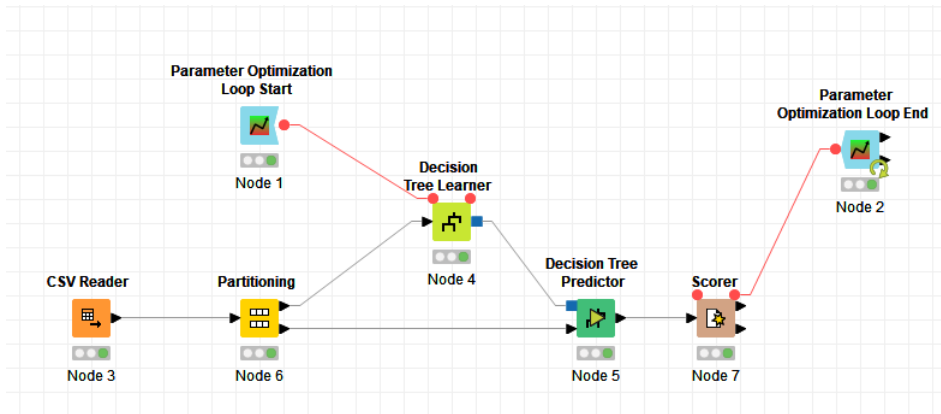

- **Gradient-based optimization**

For specific learning algorithms, it is possible to compute the gradient with respect to hyper-parameters and then optimize the hyper-parameters using gradient descent.

- **Evolutionary optimization**

uses evolutionary algorithms to search the space of hyper-parameters for a given algorithm.

# KNIME - Hyper-parameter tuning

# KNIME - Hyper-parameter tuning

The image shows a KNIME workflow on the left and a 'Parameter Optimization Loop Start' dialog box on the right. The workflow consists of three nodes: 'Node 3' (CSV Reader), 'Node 6' (Partitioning), and 'Node 1' (Parameter Optimization Loop Start). A red arrow points from Node 1 to the dialog box. The dialog box is titled 'Dialog - 3:1 - Parameter Optimization Loop Start' and has a 'File' menu. It contains three tabs: 'Standard settings', 'Flow Variables', and 'Job Manager Selection'. The 'Standard settings' tab is active and shows a table with the following data:

Parameter	Start value	Stop value	Step size	Integer?
MinNrRecords	4	20	1.0	<input checked="" type="checkbox"/>

Below the table is a '+ Add new parameter' button. At the bottom, there is a 'Search strategy' dropdown menu with the following options: 'Brute Force' (selected), 'Hillclimbing', 'Random Search', and 'Bayesian Optimization (TPE)'. There are also 'Apply', 'Cancel', and a help icon buttons at the bottom right of the dialog.

# Hyper-parameter optimization and Model Selection

- [AutoWEKA](#) is an approach for the simultaneous selection of a machine learning algorithm and its hyper-parameters; combined with the WEKA package.
- [Auto-sklearn](#) is an extension of AutoWEKA using the Python library scikit-learn which is a drop-in replacement for regular scikit-learn classifiers and regressors. It improves over AutoWEKA by using meta-learning to increase search efficiency and post-hoc ensemble building to combine the models generated during the hyperparameter optimization process.
- [TPOT](#) is a data-science assistant which optimizes machine learning pipelines using genetic programming
- [H2O AutoML](#) provides automated model selection and ensembling for the H2O machine learning and data analytics platform.
- [mlr](#) is a R package that contains several hyper-parameter optimization techniques for machine learning problems.

- [Google CLOUD AUTOML](#)

is an cloud-based machine learning service which so far provides the automated generation of computer vision pipelines.

- [Auto Keras](#)

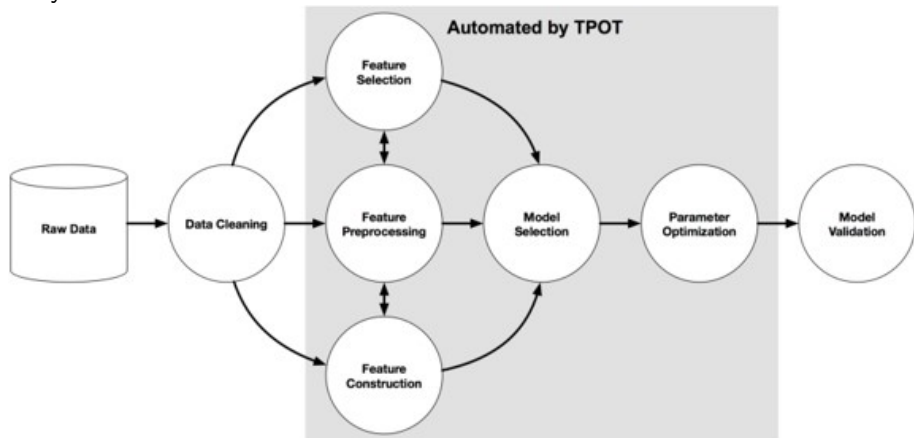

is an open-source python package for neural architecture search.

- [Automl](#)

Deep Learning with Metaheuristic

# Automated by TPOT

TPOT will automate the most tedious part of machine learning by intelligently exploring thousands of possible pipelines to find the best one for your data

# Which AutoML Tool?

A. Balaji, A. Allen Choosing the best AutoML Framework, 2020  
<https://medium.com/georgian-impact-blog/choosing-the-best-automl-framework-4f2a90cb1826>

- a selection of 87 open datasets, 30 regression and 57 classification, from [OpenML](#)
- Comparison between four frameworks: automl, auto-sklearn, TPOT, and H2O
- [Auto-sklearn](#) performs the best on the classification datasets and [TPOT](#) performs the best on regression datasets.

OpenML manifesto:

*As machine learning is enhancing our ability to understand nature and build a better future, it is crucial that we make it transparent and easily accessible to everyone in research, education and industry.*

*The Open Machine Learning project is an inclusive movement to build an open, organized, online ecosystem for machine learning.*

*We build open source tools to discover (and share) open data from any domain, easily draw them into your favourite machine learning environments, quickly build models alongside (and together with) thousands of other data scientists, analyse your results against the state of the art, and even get automatic advice on how to build better models. Stand on the shoulders of giants and make the world a better place.*
